## Abstract

We study the quantum query complexity of two problems.

First, we consider the problem of determining if a sequence of parentheses is a properly balanced one (a *Dyck word*), with a depth of at most  $k$ . We call this the  $\text{DYCK}_{k,n}$  problem. We prove a lower bound of  $\Omega(c^k \sqrt{n})$ , showing that the complexity of this problem increases exponentially in  $k$ . Here  $n$  is the length of the word. When  $k$  is a constant, this is interesting as a representative example of star-free languages for which a surprising  $\tilde{O}(\sqrt{n})$  query quantum algorithm was recently constructed by Aaronson et al. [1]. Their proof does not give rise to a general algorithm. When  $k$  is not a constant,  $\text{DYCK}_{k,n}$  is not context-free. We give an algorithm with  $O(\sqrt{n}(\log n)^{0.5k})$  quantum queries for  $\text{DYCK}_{k,n}$  for all  $k$ . This is better than the trival upper bound  $n$  for  $k = o(\frac{\log(n)}{\log \log n})$ .

Second, we consider connectivity problems on grid graphs in 2 dimensions, if some of the edges of the grid may be missing. By embedding the “balanced parentheses” problem into the grid, we show a lower bound of  $\Omega(n^{1.5-\epsilon})$  for the directed 2D grid and  $\Omega(n^{2-\epsilon})$  for the undirected 2D grid. The directed problem is interesting as a black-box model for a class of classical dynamic programming strategies including the one that is usually used for the well-known edit distance problem. We also show a generalization of this result to more than 2 dimensions.

**2012 ACM Subject Classification** Theory of computation  $\rightarrow$  Quantum query complexity

**Keywords and phrases** Quantum query complexity, Quantum algorithms, Dyck language, Grid path

**Funding** Supported by QuantERA ERA-NET Cofund in Quantum Technologies implemented within the European Union’s Horizon 2020 Programme (QuantAlgo project) and ERDF project 1.1.1.5/18/A/020 “Quantum algorithms: from complexity theory to experiment”. The research was funded by the subsidy allocated to Kazan Federal University for the state assignment in the sphere of scientific activities.

## 1 Introduction

We study the quantum query complexity of two problems:

**Quantum complexity of regular languages.** Consider the problem of recognizing whether an  $n$ -bit string belongs to a given regular language. This models a variety of computational tasks that can be described by regular languages. In the quantum case, the most commonly used model for studying the complexity of various problems is the query model. For this setting, Aaronson, Grier and Schaeffer [1] recently showed that any regular language  $L$  has one of three possible quantum query complexities on inputs of length  $n$ :  $\Theta(1)$  if the language can be decided by looking at  $O(1)$  first or last symbols of the word;  $\tilde{\Theta}(\sqrt{n})$  if

45 the best way to decide  $L$  is Grover’s search (for example, for the language consisting of all  
 46 words containing at least one letter a);  $\Theta(n)$  for languages in which we can embed counting  
 47 modulo some number  $p$  which has quantum query complexity  $\Theta(n)$ .

48 As shown in [1], a regular language being of complexity  $\tilde{O}(\sqrt{n})$  (which includes the first  
 49 two cases above) is equivalent to it being star-free. Star-free languages are defined as the  
 50 languages which have regular expressions not containing the Kleene star (if it is allowed to  
 51 use the complement operation). Star-free languages are one of the most commonly studied  
 52 subclasses of regular languages and there are many equivalent characterizations of them.  
 53 One of the star-free languages mentioned in [1] is the Dyck language (with one type of  
 54 parenthesis) with a constant bounded height. The Dyck language is the set of balanced  
 55 strings of parentheses ( and ). The language is a fundamental example of a context-free  
 56 language that is not regular. If at no point the number of opening parentheses exceeds the  
 57 number of closing parentheses by more than  $k$ , we denote the problem of determining if an  
 58 input of length  $n$  belongs to this language by  $\text{DYCK}_{k,n}$ . When more types of parenthesis  
 59 are allowed, the famous Chomsky–Schützenberger representation theorem shows that any  
 60 context-free language is the homomorphic image of the intersection of a Dyck language and  
 61 a regular language.

62 **Our results.** We show that an exponential dependence of the complexity on  $k$  is  
 63 unavoidable. Namely, for the balanced parentheses language, we have

- 64 ■ there exists  $c > 1$  such that, for all  $k \leq \log n$ , the quantum query complexity is  $\Omega(c^k \sqrt{n})$ ;
- 65 ■ If  $k = c \log n$  for an appropriate constant  $c$ , the quantum query complexity is  $\Omega(n^{1-\epsilon})$ .

66 Thus, the exponential dependence on  $k$  is unavoidable and distinguishing sequences of  
 67 balanced parentheses of length  $n$  and depth  $\log n$  is almost as hard as distinguishing sequences  
 68 of length  $n$  and arbitrary depth.

69 Similar lower bounds have recently been independently proven by Buhrman et al. [7].

70 Additionally, we give an explicit algorithm (see Theorem 3) for the decision problem  
 71  $\text{DYCK}_{k,n}$  with  $O(\sqrt{n}(\log n)^{0.5k})$  quantum queries. The algorithm also works when  $k$  is not a  
 72 constant and is better than the trivial upper bound of  $n$  when  $k = o\left(\frac{\log(n)}{\log \log n}\right)$ .

73 **Finding paths on a grid.** The second problem that we consider is graph connectivity  
 74 on subgraphs of the 2D grid. Consider a 2D grid with vertices  $(i, j)$ ,  $i \in \{0, 1, \dots, n\}$ ,  $j \in$   
 75  $\{0, 1, \dots, k\}$  and edges from  $(i, j)$  to  $(i + 1, j)$  and  $(i, j + 1)$ . The grid can be either directed  
 76 (with edges in the directions of increasing coordinates) or undirected. We are given an  
 77 unknown subgraph  $G$  of the 2D grid and we can perform queries to variables  $x_u$  (where  $u$   
 78 is an edge of the grid) defined by  $x_u = 1$  if  $u$  belongs to  $G$  and 0 otherwise. The task is to  
 79 determine whether  $G$  contains a path from  $(0, 0)$  to  $(n, k)$ .

80 Our interest in this problem is driven by the edit distance problem. In the edit distance  
 81 problem, we are given two strings  $x$  and  $y$  and have to determine the smallest number of  
 82 operations (replacing one symbol by another, removing a symbol or inserting a new symbol)  
 83 with which one can transform  $x$  to  $y$ . If  $|x| \leq n$ ,  $|y| \leq k$ , the edit distance is solvable in  
 84 time  $O(nk)$  by dynamic programming [16]. If  $n = k$  then, under the strong exponential time  
 85 hypothesis (SETH), there is no classical algorithm computing edit distance in time  $O(n^{2-\epsilon})$   
 86 for  $\epsilon > 0$  [4] and the dynamic programming algorithm is essentially optimal.

87 However, SETH does not apply to quantum algorithms. Namely, SETH asserts that there  
 88 is no algorithm for general instances of SAT that is substantially better than naive search.  
 89 Quantumly, a simple use of Grover’s search gives a quadratic advantage over naive search.  
 90 This leads to the question: can this quadratic advantage be extended to edit distance (and  
 91 other problems that have lower bounds based on SETH)?

92 Since edit distance is quite important in classical algorithms, the question about its  
 93 quantum complexity has attracted a substantial interest from various researchers. Boroujeni  
 94 et al. [6] invented a better-than-classical quantum algorithm for approximating the edit  
 95 distance which was later superseded by a better classical algorithm of [8]. However, there  
 96 has been no quantum algorithms computing the edit distance exactly (which is the most  
 97 important case).

98 The main idea of the classical algorithm for edit distance is as follows:

99 ■ We construct a weighted version of the directed 2D grid (with edge weights 0 and 1) that  
 100 encodes the edit distance problem for strings  $x$  and  $y$ , with the edit distance being equal  
 101 to the length of the shortest directed path from  $(0, 0)$  to  $(n, k)$ .

102 ■ We solve the shortest path problem on this graph and obtain the edit distance.

103 As a first step, we can study the question of whether the shortest path is of length 0 or more  
 104 than 0. Then, we can view edges of length 0 as present and edges of length 1 as absent. The  
 105 question “Is there a path of length 0?” then becomes “Is there a path from  $(0, 0)$  to  $(n, k)$   
 106 in which all edges are present?”. A lower bound for this problem would imply a similar lower  
 107 bound for the shortest path problem and a quantum algorithm for it may contain ideas that  
 108 would be useful for a shortest path quantum algorithm.

109 **Our results.** We use our lower bound on the balanced parentheses language to show an  
 110  $\Omega(n^{1.5-\epsilon})$  lower bound for the connectivity problem on the directed 2D grid. This shows a  
 111 limit on quantum algorithms for finding edit distance through the reduction to shortest paths.  
 112 More generally, for an  $n \times k$  grid ( $n > k$ ), our proof gives a lower bound of  $\Omega((\sqrt{nk})^{1-\epsilon})$ .

113 The trivial upper bound is  $O(nk)$  queries, since there are  $O(nk)$  variables. There is  
 114 no nontrivial quantum algorithm, except for the case when  $k$  is very small. Then, the  
 115 connectivity problem can be solved with  $O(\sqrt{n} \log^k n)$  quantum queries [11]<sup>1</sup> but this bound  
 116 becomes trivial already for  $k = \Omega(\frac{\log n}{\log \log n})$ .

117 For the undirected 2D grid, we show a lower bound of  $\Omega((nk)^{1-\epsilon})$ , whenever  $k \geq \log n$ .  
 118 Thus, the naive algorithm is almost optimal in this case. We also extend both of these  
 119 results to higher dimensions, obtaining a lower bound of  $\Omega((n_1 n_2 \dots n_d)^{1-\epsilon})$  for an undirected  
 120  $n_1 \times n_2 \times \dots \times n_d$  grid in  $d$  dimensions and a lower bound of  $\Omega(n^{(d+1)/2-\epsilon})$  for a directed  
 121  $n \times n \times \dots \times n$  grid in  $d$  dimensions.

122 In a recent work, an  $\Omega(n^{1.5})$  lower bound for edit distance was shown by Buhrman et al.  
 123 [7], assuming a quantum version of the Strong Exponential Time hypothesis (QSETH). As  
 124 part of this result they give an  $\Omega(n^{1.5})$  query lower bound for a different path problem on a  
 125 2D grid. Then QSETH is invoked to prove that no quantum algorithm can be faster than  
 126 the best algorithm for this shortest path problem. Neither of the two results follow directly  
 127 one from another, as different shortest path problems are used.

## 128 2 Definitions

129 For a word  $x \in \Sigma^*$  and a symbol  $a \in \Sigma$ , let  $|x|_a$  be the number of occurrences of  $a$  in  $x$ .

130 For two (possibly partial) Boolean functions  $g : G \rightarrow \{0, 1\}$ , where  $G \subseteq \{0, 1\}^n$ , and  
 131  $h : H \rightarrow \{0, 1\}$ , where  $H \subseteq \{0, 1\}^m$ , we define the composed function  $g \circ h : D \rightarrow \{0, 1\}$ ,  
 132 with  $D \subseteq \{0, 1\}^{nm}$ , as  $(g \circ h)(x) = g(h(x_1, \dots, x_m), \dots, h(x_{(n-1)m+1}, \dots, x_{nm}))$ . Given a  
 133 Boolean function  $f$  and a nonnegative integer  $d$ , we define  $f^d$  recursively as  $f$  iterated  $d$   
 134 times:  $f^d = f \circ f^{d-1}$  with  $f^1 = f$ .

<sup>1</sup> Aaronson et al. [1] also give a bound of  $O(\sqrt{n} \log^{m-1} n)$  but in this case  $m$  is the rank of the syntactic monoid which can be exponentially larger than  $k$ .

135 **Quantum query model.** We use the standard form of the quantum query model. Let  
 136  $f : D \rightarrow \{0, 1\}$ ,  $D \subseteq \{0, 1\}^n$  be an  $n$  variable function we wish to compute on an input  $x \in D$ .  
 137 We have an oracle access to the input  $x$  — it is realized by a specific unitary transformation  
 138 usually defined as  $|i\rangle|z\rangle|w\rangle \rightarrow |i\rangle|z + x_i \pmod{2}\rangle|w\rangle$  where the  $|i\rangle$  register indicates the  
 139 index of the variable we are querying,  $|z\rangle$  is the output register, and  $|w\rangle$  is some auxiliary  
 140 work-space. An algorithm in the query model consists of alternating applications of arbitrary  
 141 unitaries independent of the input and the query unitary, and a measurement in the end.  
 142 The smallest number of queries for an algorithm that outputs  $f(x)$  with probability  $\geq \frac{2}{3}$  on  
 143 all  $x$  is called the quantum query complexity of the function  $f$  and is denoted by  $Q(f)$ .

144 Let a symmetric matrix  $\Gamma$  be called an adversary matrix for  $f$  if the rows and columns of  
 145  $\Gamma$  are indexed by inputs  $x \in D$  and  $\Gamma_{xy} = 0$  if  $f(x) \neq f(y)$ . Let  $\Gamma^{(i)}$  be a similarly sized matrix  
 146 such that  $\Gamma_{xy}^{(i)} = \begin{cases} \Gamma_{xy} & \text{if } x_i \neq y_i \\ 0 & \text{otherwise} \end{cases}$ . Then let  $Adv^\pm(f) = \max_{\Gamma - \text{an adversary matrix for } f} \frac{\|\Gamma\|}{\max_i \|\Gamma^{(i)}\|}$

147 be called the adversary bound and let  $Adv(f) = \max_{\substack{\Gamma - \text{an adversary matrix for } f \\ \Gamma - \text{nonnegative}}} \frac{\|\Gamma\|}{\max_i \|\Gamma^{(i)}\|}$  be

148 called the positive adversary bound. The following facts will be relevant for us:  $Adv(f) \leq$   
 149  $Adv^\pm(f)$ ;  $Q(f) = \Theta(Adv^\pm(f))$  [14];  $Adv^\pm$  composes exactly even for partial Boolean func-  
 150 tions  $f$  and  $g$ , meaning,  $Adv^\pm(f \circ g) = Adv^\pm(f) \cdot Adv^\pm(g)$  [10, Lemma 6]

151 **Reductions.** We will say that a Boolean function  $f$  is reducible to  $g$  and denote it by  
 152  $f \leq g$  if there exists an algorithm that given an oracle  $O_x$  for an input of  $f$  transforms it into  
 153 an oracle  $O_y$  for  $g$  using at most  $O(1)$  calls of oracle  $O_x$  such that  $f(x)$  can be computed  
 154 from  $g(y)$ . Therefore, from  $f \leq g$  we conclude that  $Q(f) \leq Q(g)$  because one can compute  
 155  $f(x)$  using the algorithm for  $g(y)$  and the reduction algorithm that maps  $x$  to  $y$ .

156 **Dyck languages of bounded depth.** Let  $\Sigma$  be an alphabet consisting of two symbols:  
 157 ( and ). The Dyck language  $L$  consists of all  $x \in \Sigma^*$  that represent a correct sequence of  
 158 opening and closing parentheses. We consider languages  $L_k$  consisting of all words  $x \in L$   
 159 where the number of opening parentheses that are not closed yet never exceeds  $k$ . The  
 160 language  $L_k$  corresponds to a query problem  $DYCK_{k,n}(x_1, \dots, x_n)$  where  $x_1, \dots, x_n \in \{0, 1\}$   
 161 describe a word of length  $n$  in the natural way: the  $i^{\text{th}}$  symbol of  $x$  is ( if  $x_i = 0$  and ) if  $x_i = 1$ .  
 162  $DYCK_{k,n}(x) = 1$  iff the word  $x$  belongs to  $L_k$ . For all  $x \in \{0, 1\}^n$ , we define  $f(x) = |x|_0 - |x|_1$ ,  
 163 we call it the **balance**. We define a  $+k$ -substring (resp.  $-k$ -substring) as a substring whose  
 164 balance is equal to  $k$  (resp. equal to  $-k$ ). A  $\pm k$ -substring is a substring whose balance is  
 165 equal to  $k$  in absolute value. For all  $0 \leq i \leq j \leq n - 1$ , we define  $x[i, j] = x_i, x_{i+1}, \dots, x_j$ .  
 166 Finally, we define  $h(x) = \max_{0 \leq i \leq n-1} f(x[0, i])$  and  $h^-(x) = \min_{0 \leq i \leq n-1} f(x[0, i])$ . A  
 167 substring  $x[i, j]$  is *minimal* if it does not contain a substring  $x[i', j']$  such that  $(i, j) \neq (i', j')$ ,  
 168 and  $f(x[i', j']) = f(x[i, j])$ .

169 **Connectivity on a directed 2D grid.** Let  $G_{n,k}$  be a directed version of an  $n \times k$  grid  
 170 in two dimensions, with vertices  $(i, j)$ ,  $i \in [n]$ ,  $j \in [k]$  and directed edges from  $(i, j)$  to  $(i+1, j)$   
 171 (if  $i < n$ ) and from  $(i, j)$  to  $(i, j+1)$  (if  $j < k$ ). If  $G$  is a subgraph of  $G_{n,k}$ , we can describe it by  
 172 variables  $x_e$  corresponding to edges  $e$  of  $G_{n,k}$ :  $x_e = 1$  if the edge  $e$  belongs to  $G$  and  $x_e = 0$  oth-  
 173 erwise. We consider a problem DIRECTED-2D-CONNECTIVITY in which one has to determine  
 174 if  $G$  contains a path from  $(0, 0)$  to  $(n, k)$ :  $DIRECTED-2D-CONNECTIVITY_{n,k}(x_1, \dots, x_m) = 1$   
 175 (where  $m$  is the number of edges in  $G_{n,k}$ ) iff such a path exists.

176 **Connectivity on an undirected 2D grid.** Let  $G_{n,k}$  be an undirected  $n \times k$  grid and  
 177 let  $G$  be a subgraph of  $G_{n,k}$ . We describe  $G$  by variables  $x_e$  in a similar way and define  
 178  $UNDIRECTED-2D-CONNECTIVITY_{n,k}(x_1, \dots, x_m) = 1$  iff  $G$  contains a path from  $(0, 0)$  to  
 179  $(n, k)$ . We also consider  $d$  dimensional versions of these two problems, on  $n \times n \times \dots \times n$   
 180 grids (with the grid being of the same length in all the dimensions). In the directed version

181 (DIRECTED-dD-CONNECTIVITY), we have a subgraph  $G$  of a directed grid (with edges direc-  
 182 ted in the directions from  $(0, \dots, 0)$  to  $(n, \dots, n)$ ) and  $\text{DIRECTED-dD-CONNECTIVITY}(x_1, \dots, x_m) =$   
 183 1 iff  $G$  contains a directed path from  $(0, \dots, 0)$  to  $(n, \dots, n)$ . The undirected version is defined  
 184 similarly, with an undirected grid instead of a directed one.

### 185 **3 A quantum algorithm for membership testing of Dyck $_{k,n}$**

186 In this section, we give a quantum algorithm for  $\text{DYCK}_{k,n}(x)$ , where  $k$  can be a function of  
 187  $n$ . The general idea is that  $\text{DYCK}_{k,n}(x) = 0$  if and only if one of the following conditions  
 188 holds: (i)  $x$  contains a  $+(k+1)$ -substring; (ii)  $x$  contains a substring  $x[0, i]$  such that the  
 189 balance  $f(x[0, i]) = -1$ ; (iii) the balance of the entire word  $f(x) \neq 0$ .

#### 190 **3.1 $\pm k$ -Substring Search algorithm**

191 The goal of this section is to describe a quantum algorithm which searches for a substring  
 192  $x[i, j]$  that has a balance  $f(x[i, j]) \in \{+k, -k\}$  for some integer  $k$ . Throughout this section,  
 193 we find and consider only **minimal** substrings. A substring is minimal if it does not contain  
 194 a proper substring with the same balance. Throughout this section we use the following  
 195 easily verifiable facts:

- 196 ■ For any two minimal  $\pm k$ -substrings  $x[i, j]$  and  $x[k, l]$ :  $i < k \implies j < l$ . This induces a  
 197 natural linear order among all  $\pm k$ -substrings according to their starting (or, equivalently,  
 198 ending) positions.
- 199 ■ Minimal  $+k$ -substrings do not intersect with minimal  $-k$ -substrings.
- 200 ■ If  $x[l_1, r_1]$  and  $x[l_2, r_2]$  with  $l_1 < l_2$  are two **consecutive** minimal  $(k-1)$ -substrings and  
 201 their signs are the same, then  $x[l_1, r_2]$  is a  $k$ -substring with this sign.

202 This algorithm is the basis of our algorithms for  $\text{DYCK}_{k,n}$ . The algorithm works in a recursive  
 203 way. It searches for two consecutive minimal  $\pm(k-1)$ -substrings  $x[l_1, r_1]$  and  $x[l_2, r_2]$  such  
 204 that they either overlap or there are no  $\pm(k-1)$ -substrings between them. If both substrings  
 205  $x[l_1, r_1]$  and  $x[l_2, r_2]$  are  $+(k-1)$ -substrings, then we get a minimal  $+k$ -substring in total. If  
 206 both substrings are  $-(k-1)$ -substrings, then we get a minimal  $-k$ -substring in total.

207 We first discuss three building blocks for our algorithm. The first one is  $\text{FINDATLEFTMOST}_k(l, r, t, d, s)$   
 208 and accepts as inputs: the borders  $l$  and  $r$ , where  $l$  and  $r$  are integers such that  $0 \leq l \leq r \leq$   
 209  $n-1$ ; a position  $t \in \{l, \dots, r\}$ ; a maximal length  $d$  for the substring, where  $d$  is an integer  
 210 such that  $0 < d \leq r-l+1$ ; the sign of the balance  $s \in \{+1, -1\}$ .  $+1$  is used for searching for  
 211 a  $+k$ -substring,  $-1$  is used for searching for a  $-k$ -substring,  $\{+1, -1\}$  is used for searching  
 212 for both. It outputs a triple  $(i, j, \sigma)$  such that  $t \in [i, j]$ ,  $j-i+1 \leq d$ ,  $f(x[i, j]) \in \{+k, -k\}$   
 213 and  $\sigma = \text{sign}(f(x[i, j])) \in s$ . The substring should be the leftmost one that contains  $t$ , i.e.  
 214 there is no other minimal  $x[i', j']$  such that  $i' < i$ ,  $t \in [i', j']$ ,  $f(x[i', j']) = f(x[i, j])$ . If no  
 215 such substrings have been found, the algorithm returns NULL.

216 The second one is  $\text{FINDATRIGHTMOST}_k$ . It is similar to the  $\text{FINDATLEFTMOST}_k$ , but  
 217 finds the rightmost  $\pm k$ -substring, i.e. there is no other minimal  $x[i', j']$  such that  $j' > j$ ,  
 218  $t \in [i', j']$ ,  $f(x[i', j']) = f(x[i, j])$

219 The third one is  $\text{FINDFIRST}_k(l, r, s, \text{direction})$  and accepts as inputs: the borders  $l$  and  $r$ ,  
 220 where  $l$  and  $r$  are integers such that  $0 \leq l \leq r \leq n-1$ ; the sign of the balance  $s \in \{+1, -1\}$ .  
 221 a *direction*  $\in \{\text{left}, \text{right}\}$ . When the direction is right (respectively left),  $\text{FINDFIRST}_k$  finds  
 222 the first  $\pm k$ -substring from the left to the right (respectively from the right to the left) in  
 223  $[l, r]$  of sign  $s$ .

224 These three building blocks are interdependent since  $\text{FINDATLEFTMOST}_k$  uses  $\text{FINDFIRST}_{k-1}$   
 225 and  $\text{FINDATRIGHTMOST}_{k-1}$  as subroutines,  $\text{FINDFIRST}_k$  uses  $\text{FINDATLEFTMOST}_k$  and

226 FINDATRIGHTMOST $_k$  as subroutines. A description of FINDATLEFTMOST $_k(l, r, t, d, s)$  fol-  
 227 lows. The algorithm is presented in Appendix A. The description of FINDATRIGHTMOST $_k(l, r, t, d, s)$   
 228 is similar and is omitted.

229 When  $k = 2$ , the procedure FINDATLEFTMOST $_2(l, r, t, d, s)$  checks that  $x_t = x_{t-1}$  and  
 230  $\text{sign}(f(x[t-1, t])) \in s$ . If yes, it has found the substring. Otherwise, it checks if  $x_t = x_{t+1}$   
 231 and  $\text{sign}(f(x[t, t+1])) \in s$ . If both checks fail, the procedure returns NULL. For  $k > 2$  the  
 232 procedure is the following.

233 **Step 1.** Check whether  $t$  is inside a  $\pm(k-1)$ -substring of length at most  $d-1$ , i.e.  
 234  $v = (i, j, \sigma) \leftarrow \text{FINDATLEFTMOST}_{k-1}(l, r, t, d-1, \{+1, -1\})$ . If  $v \neq \text{NULL}$ , then  $(i_1, j_1, \sigma_1) \leftarrow$   
 235  $(i, j, \sigma)$  and the algorithm goes to Step 2. Otherwise, the algorithm goes to Step 6.  
 236 **Step 2.** Check whether  $i_1 - 1$  is inside a  $\pm(k-1)$ -substring of length at most  $d-1$  and choose  
 237 the rightmost one:  $v = (i, j, \sigma) \leftarrow \text{FINDATRIGHTMOST}_{k-1}(l, r, i_1 - 1, d-1, \{+1, -1\})$ .  
 238 If  $v = \text{NULL}$ , then the algorithm goes to Step 3. If  $v \neq \text{NULL}$  and  $\sigma = \sigma_1$ , then  
 239  $(i_2, j_2, \sigma_2) \leftarrow (i, j, \sigma)$  and go to Step 8. Otherwise, go to Step 4.  
 240 **Step 3.** Search for the first  $\pm(k-1)$ -substring on the left from  $i_1 - 1$  at distance at most  $d$ ,  
 241 i.e.  $v = (i, j, \sigma) \leftarrow \text{FINDFIRST}_{k-1}(\min(l, j_1 - d + 1), i_1 - 1, \{+1, -1\}, \text{left})$ . If  $v \neq \text{NULL}$   
 242 and  $\sigma_1 = \sigma$ , then  $(i_2, j_2, \sigma_2) \leftarrow (i, j, \sigma)$  and go to Step 8. Otherwise, go to Step 4.  
 243 **Step 4.** Check whether  $j_1 + 1$  is inside a  $\pm(k-1)$ -substring of length at most  $d-1$ , i.e.  
 244  $v = (i, j, \sigma) \leftarrow \text{FINDATLEFTMOST}_{k-1}(l, r, j_1 + 1, d-1, \{+1, -1\})$ .  
 245 If  $v \neq \text{NULL}$ , then  $(i_2, j_2, \sigma_2) \leftarrow (i, j, \sigma)$  and go to Step 8. Otherwise, go to Step 5.  
 246 **Step 5.** Search for the first  $\pm(k-1)$ -substring on the right from  $j_1 + 1$  at distance at most  
 247  $d$ , i.e.  $v = (i, j, \sigma) \leftarrow \text{FINDFIRST}_{k-1}(j_1 + 1, \min(i_1 + d - 1, r), \{+1, -1\}, \text{right})$ .  
 248 If  $v \neq \text{NULL}$ , then  $(i_2, j_2, \sigma_2) \leftarrow (i, j, \sigma)$ , then go to Step 8. Otherwise, return NULL.  
 249 **Step 6.** Search for the first  $\pm(k-1)$ -substring on the right at distance at most  $d$  from  $t$ , i.e.  
 250  $v = (i, j, \sigma) \leftarrow \text{FINDFIRST}_{k-1}(t, \min(t + d - 1, r), \{+1, -1\}, \text{right})$   
 251 If  $v \neq \text{NULL}$ , then  $(i_1, j_1, \sigma_1) \leftarrow (i, j, \sigma)$  and go to Step 7. Otherwise, returns NULL.  
 252 **Step 7.** Search for the first  $\pm(k-1)$ -substring on the left from  $t$  at distance at most  $d$ , i.e.  
 253  $v = (i, j, \sigma) \leftarrow \text{FINDFIRST}_{k-1}(\max(l, t - d + 1), t, \{+1, -1\}, \text{left})$   
 254 If  $v \neq \text{NULL}$ , then  $(i_2, j_2, \sigma_2) \leftarrow (i, j, \sigma)$  and go to Step 8. Otherwise, returns NULL.  
 255 **Step 8.** If  $\sigma_1 = \sigma_2$ ,  $\sigma_1 \in s$  and  $\max(j_1, j_2) - \min(i_1, i_2) + 1 \leq d$ , output  $(\min(i_1, i_2), \max(j_1, j_2), \sigma_1)$ ,  
 256 otherwise return NULL.

257 By construction and induction on  $k$ , the two  $\pm(k-1)$ -substrings  $x[i_1, j_1]$  and  $x[i_2, j_2]$   
 258 (if they exist) involved in the procedure FINDATLEFTMOST $_k$  are always consecutive and  
 259 minimal. FINDATLEFTMOST $_k$  thus returns a  $\pm k$ -substring, if both substrings have the same  
 260 sign.

261 Using this basic procedure, we then search for a  $\pm k$ -substring by searching for a  $t$  and  
 262  $d$  such that FINDATLEFTMOST $_k(l, r, t, d, s)$  returns a non-NULL value. Unfortunately, our  
 263 algorithms have two-sided bounded error: they can, with small probability, return NULL  
 264 even if a substring exists or return a wrong substring instead of NULL. In this setting,  
 265 Grover's search algorithm is not directly applicable and we need to use a more sophisticated  
 266 search [9]. Furthermore, simply applying the search algorithm naively does not give the right  
 267 complexity. Indeed, if we search for a substring of length roughly  $d$  (say between  $d$  and  $2d$ ),  
 268 we can find one with expected running time  $O(\sqrt{(r-l)/d})$  because at least  $d$  values of  $t$   
 269 will work. On the other hand, if there are no such substrings, the expected running time  
 270 will be  $O(\sqrt{r-l})$ . Intuitively, we can do better because if there is a substring of length at  
 271 least  $d$  then there are at least  $d$  values of  $t$  that work. Hence, we only need to distinguish  
 272 between no solutions, or at least  $d$ . This allows to stop the Grover iteration early and make  
 273  $O(\sqrt{(r-l)/d})$  queries in all cases.

274 ► **Lemma 1** (Modified from [9], Appendix B). *Given  $n$  algorithms, quantum or classical, each*  
 275 *computing some bit-value with bounded error probability, and some  $T \geq 1$ , there is a quantum*  
 276 *algorithm that uses  $O(\sqrt{n/T})$  queries and with constant probability: returns the index of*  
 277 *a “1”, if there are at least  $T$  “1s” among the  $n$  values; returns NULL if there are no “1”;*  
 278 *returns anything otherwise.*

279 The algorithm that uses above ideas is presented in Algorithm 1.

■ **Algorithm 1** FINDFIXEDLEN $_k(l, r, d, s)$ . Search for any  $\pm k$ -substring of length  $\in [d/2, d]$

---

Find  $t$  such that  $v_t \leftarrow \text{FINDATLEFTMOST}_k(l, r, t, d, s) \neq \text{NULL}$  using Lemma 1 with  $T = d/2$ .

**return**  $v_t$  or NULL if none.

---

280 We can then write an algorithm FINDANY $_k(l, r, s)$  that searches for any  $\pm k$ -substring. We  
 281 consider a randomized algorithm that uniformly chooses a of power 2 from  $[2^{\lceil \log_2 k \rceil}, (r-l)]$ ,  
 282 i.e.  $d \in \{2^{\lceil \log_2 k \rceil}, 2^{\lceil \log_2 k \rceil + 1}, \dots, 2^{\lceil \log_2(r-l) \rceil}\}$ . For the chosen  $d$ , we run Algorithm 1. So, the  
 283 algorithm will succeed with probability at least  $O(1/\log(r-l))$ . We can apply Amplitude  
 284 amplification and ideas from Lemma 1 to this and get an algorithm that uses  $O(\sqrt{\log(r-l)})$   
 285 iterations.

■ **Algorithm 2** FINDANY $_k(l, r, s)$ . Search for any  $\pm k$ -substring.

---

Find  $d \in \{2^{\lceil \log_2 k \rceil}, 2^{\lceil \log_2 k \rceil + 1}, \dots, 2^{\lceil \log_2(r-l) \rceil}\}$  such that:

$v_d \leftarrow \text{FINDFIXEDLEN}_k(l, r, d, s) \neq \text{NULL}$  using amplitude amplification.

**return**  $v_d$  or NULL if none.

---

286 Finally, we present the algorithm that finds the first  $\pm k$ -substring – FINDFIRST $_k$ . Let  
 287 us consider the case *direction = right*. We first find the smallest segment from the left to  
 288 the right such that its length  $w$  is a power of 2 and it contains a  $\pm k$ -substring. We do so by  
 289 doubling the length of the segment until we find a  $\pm k$ -substring. We now have a segment  
 290 that contains a  $\pm k$ -substring and we want to find the leftmost one. We do so by the following  
 291 variant of binary search. At each step let  $mid = \lfloor (lBorder + rBorder)/2 \rfloor$  be the middle of  
 292 the search segment  $[lBorder, rBorder]$ . There are three cases:

- 293 ■ There is a  $k$ -substring in  $[lBorder, mid]$ , then the leftmost  $k$ -substring is in this segment.
- 294 ■ There are no  $k$ -substrings in  $[lBorder, mid]$ , but  $mid$  is inside a  $k$ -substring. Then the  
 295 leftmost  $k$ -substring that contains  $mid$  is the required substring.
- 296 ■ There are no  $k$ -substrings in  $[lBorder, mid]$  and  $mid$  is not inside a  $k$ -substring. Then  
 297 the required substring is in  $[mid + 1, rBorder]$ .

298 Each iteration of the loop the algorithm halves the search space or finds the first  $k$ -  
 299 substring itself if it contains  $mid$ . If *direction = left*, we replace FINDATLEFTMOST $_k$   
 300 by FINDATRIGHTMOST $_k$  that finds the rightmost  $\pm k$ -substring that contains  $mid$ . A  
 301 detailed description of this algorithm is presented in Appendix C.

302 ► **Proposition 2.** *For any  $\varepsilon > 0$  and  $k$ , algorithms FINDATLEFTMOST $_k$ , FINDFIXEDLEN $_k$ ,  
 303 FINDANY $_k$  and FINDFIRST $_k$  have two-sided error probability  $\varepsilon < 0.5$  and return, when  
 304 correct:*

- 305 ■ *If  $t$  is inside a  $\pm k$ -substring of sign  $s$  of length at most  $d$  in  $x[l, r]$ , then FINDATLEFTMOST $_k$   
 306 will return such a substring, otherwise it returns NULL. The running time is  $O(\sqrt{d}(\log(r-l))^{0.5(k-2)})$ .*  
 307

- 308 ■ **FINDFIXEDLEN<sub>k</sub>** either returns a  $\pm k$ -substring of sign  $s$  and length at most  $d$  in  $x[l, r]$ , or  
 309 NULL. It is only guaranteed to return a substring if there exists  $\pm k$ -substring of length at  
 310 least  $d/2$ , otherwise it can return NULL. The running time is  $O(\sqrt{r-l}(\log(r-l))^{0.5(k-2)})$ .  
 311 ■ **FINDANY<sub>k</sub>** returns any  $\pm k$ -substring of sign  $s$  in  $x[l, r]$ , otherwise it returns NULL. The  
 312 running time is  $O(\sqrt{r-l}(\log(r-l))^{0.5(k-1)})$ .  
 313 ■ **FINDFIRST<sub>k</sub>** returns the first  $\pm k$ -substring of sign  $s$  in  $x[l, r]$  in the specified direction,  
 314 otherwise it returns NULL. The running time is  $O(\sqrt{r-l}(\log(r-l))^{0.5(k-1)})$ .

315 **Proof.** We prove the result by induction on  $k$ . The base case of  $k = 2$  is obvious because of  
 316 simplicity of **FINDATLEFTMOST<sub>2</sub>** and **FINDATRIGHTMOST<sub>2</sub>** procedures. We first prove the  
 317 correctness of all the algorithms, assuming there are no errors. At the end we explain how to  
 318 deal with the errors.

319 **We start with FindAtLeftmost<sub>k</sub>:** there are different cases to be considered when  
 320 searching for a  $+k$ -substring  $x[i, j]$  of length  $\leq d$ .

321 1. Assume that there are  $j_1$  and  $i_2$  such that  $i < j_1 < i_2 < j$ ,  $|f(x[i, j_1])| = |f(x[i_2, j])| = k-1$   
 322 and  $\text{sign}(f(x[i, j_1])) = \text{sign}(f(x[i_2, j])) \in s$ . If  $t \in \{i_2, \dots, j\}$ , then the algorithm finds  
 323  $x[i_2, j]$  in Step 1 and the first invocation of **FINDFIRST<sub>k-1</sub>** in Step 3 finds  $x[i, j_1]$ . If  
 324  $t \in \{i, \dots, j_1\}$ , then the algorithm finds  $x[i, j_1]$  in Step 1 and the second invocation  
 325 of **FINDFIRST<sub>k-1</sub>** in Step 5 finds  $x[i_2, j]$ . If  $j_1 < t < i_2$ , then the third invocation of  
 326 **FINDFIRST<sub>k-1</sub>** in Step 6 finds  $x[i_2, j]$  and the fourth invocation of **FINDFIRST<sub>k-1</sub>** in Step  
 327 7 finds  $x[i, j_1]$ .

328 2. Assume that there are  $j_1$  and  $i_2$  such that  $i < i_2 < j_1 < j$ ,  $|f(x[i, j_1])| = |f(x[i_2, j])| = k-1$   
 329 and  $\text{sign}(f(x[i, j_1])) = \text{sign}(f(x[i_2, j])) \in s$ . If  $t \in \{i, \dots, j_1\}$ , then the algorithm finds  
 330  $x[i, j_1]$  in Step 1. After that, it finds  $x[i_2, j]$  in Step 4. If  $t \in \{j_1 + 1, \dots, j\}$ , then the  
 331 algorithm finds  $x[i_2, j]$  in Step 1. After that, it finds  $x[i, j_1]$  in Step 2.

332 By induction, the running time of each **FINDATLEFTMOST<sub>k-1</sub>** invocation is  $O(\sqrt{d}(\log(r-l))^{0.5(k-3)})$ , and the running time of each **FINDFIRST<sub>k-1</sub>** invocation is  $O(\sqrt{d}(\log(r-l))^{0.5(k-2)})$ .

334 **We now look at FindFixedLen<sub>k</sub>:** by construction and definition of **FINDATLEFTMOST<sub>k</sub>**,  
 335 if the algorithm returns a value, it is a valid substring (with high probability). If there exists  
 336 a substring of length at least  $d/2$ , then any query to **FINDATLEFTMOST<sub>k</sub>** with a value of  $t$   
 337 in this interval will succeed, hence there are at least  $d/2$  solutions. Therefore, by Lemma 1,  
 338 the algorithm will find one with high probability and make  $O\left(\sqrt{\frac{r-l}{d/2}}\right)$  queries. Each query  
 339 has complexity  $O(\sqrt{d}(\log(r-l))^{0.5(k-2)})$  by the previous paragraph, hence the running time  
 340 is bounded by  $O(\sqrt{r-l}(\log(r-l))^{0.5(k-2)})$ .

341 **We can now analyze FindAny<sub>k</sub>:** Assume that the shortest  $\pm k$ -substring  $x[i, j]$  is of  
 342 length  $g = j - i + 1$ . Therefore, there is a  $d$  such that  $d \leq g \leq 2d$  and the **FINDFIXEDLEN<sub>k</sub>**  
 343 procedure returns a substring for this  $d$  with constant success probability. So, the success  
 344 probability of the randomized algorithm is at least  $O(1/\log(l-r))$ . Therefore, the amplitude  
 345 amplification does  $O(\sqrt{\log(r-l)})$  iterations. The running time of **FINDFIXEDLEN<sub>k</sub>** is  
 346  $O(\sqrt{r-l}(\log(r-l))^{0.5(k-2)})$  by induction, hence the total running time is  $O(\sqrt{r-l}(\log(r-l))^{0.5(k-2)}\sqrt{\log(l-r)}) = O(\sqrt{r-l}(\log(r-l))^{0.5(k-1)})$ .  
 347

348 **Finally, we analyze FindFirst<sub>k</sub>:** See Appendix C.

349 **We now turn to error analysis.** The case of **FINDATLEFTMOST<sub>k</sub>** is easy: the al-  
 350 gorithm makes at most 5 recursive calls, each having a success probability of  $1 - \varepsilon$ . Hence it  
 351 will succeed with probability  $(1 - \varepsilon)^5$ . We can boost this probability to  $1 - \varepsilon$  by repeating  
 352 this algorithm a constant number of times. Note that this constant depends on  $\varepsilon$ .

353 The analysis of **FINDFIXEDLEN<sub>k</sub>** follows directly from [9] and Lemma 1: since **FINDATLEFTMOST<sub>k</sub>**  
 354 has two-sided error  $\varepsilon$ , there exists a search algorithm with two-sided error  $\varepsilon$ . ◀

### 3.2 The Algorithm for Dyck<sub>k,n</sub>

To solve DYCK<sub>k,n</sub>, we modify the input  $x$ . As the new input we use  $x' = 1^k x 0^k$ . DYCK<sub>k,n</sub>( $x$ ) = 1 iff there are no  $\pm(k+1)$ -substrings in  $x'$ . This idea is presented in Algorithm 3.

**Algorithm 3** DYCK<sub>k,n</sub>( $\cdot$ ). The Quantum Algorithm for DYCK<sub>k,n</sub>.

---

```

 $x \leftarrow 1^k x 0^k$ 
 $v = \text{FINDANY}_{(k+1)}(0, n + 2k - 1, \{+1, -1\})$ 
return  $v == \text{NULL}$ 

```

---

► **Theorem 3** (Appendix D). *Algorithm 3 solves DYCK<sub>k,n</sub> and the running time of Algorithm 3 is  $O(\sqrt{n}(\log n)^{0.5k})$ . The algorithm has two-side error probability  $\varepsilon < 0.5$ .*

## 4 Lower bounds for Dyck languages

► **Theorem 4.** *There exist constants  $c_1, c_2 > 0$  such that  $Q(\text{DYCK}_{c_1 \ell m, c_2 (2m)^\ell}) = \Omega(m^\ell)$ .*

**Proof.** We will use the partial Boolean function  $\text{EX}_m^{a|b} = \begin{cases} 1, & \text{if } |x|_0 = a \\ 0, & \text{if } |x|_0 = b. \end{cases}$

We prove the theorem by a reduction  $(\text{EX}_{2m}^{m|m+1})^\ell \leq \text{DYCK}_{c_1 \ell m, c_2 (2m)^\ell}$ , with the reduction described in appendix E. It is known that  $\text{Adv}^\pm(\text{EX}_{2m}^{m|m+1}) \geq \text{Adv}(\text{EX}_{2m}^{m|m+1}) > m$  [2, Theorem 5.4]. The Adversary bound composes even for partial Boolean functions [10, Lemma 1], therefore  $Q((\text{EX}_{2m}^{m|m+1})^\ell) = \Omega(m^\ell)$ . Via the reduction the same bound applies to  $\text{DYCK}_{c_1 \ell m, c_2 (2m)^\ell}$ . ◀

► **Theorem 5.** *For any  $\varepsilon > 0$ , there exists  $c > 0$  such that  $Q(\text{DYCK}_{c \log n, n}) = \Omega(n^{1-\varepsilon})$ .*

**Proof.** For any  $\varepsilon > 0$ , there exists an  $m$  such that  $\text{Adv}^\pm(\text{EX}_{2m}^{m|m+1}) \geq (2m)^{1-\varepsilon}$ . Without loss of generality we may assume that  $(2m)^\ell = n$ . From Theorem 4 with  $\ell = \log_{2m} n$  we obtain  $c_2 (2m)^\ell = c_2 n$  and height  $c_1 m \ell = \Theta(\log n)$ . The query complexity is at least  $((2m)^{1-\varepsilon})^\ell = ((2m)^\ell)^{1-\varepsilon} = n^{1-\varepsilon}$ . Therefore  $Q(\text{DYCK}_{c \log n, n}) = \Omega(n^{1-\varepsilon})$ . ◀

For constant depths the following bound can be derived:

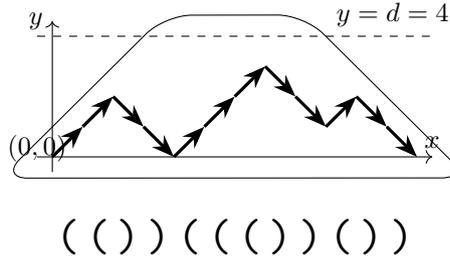

► **Theorem 6.** *There exists a constant  $c_1 > 0$  such that  $Q(\text{DYCK}_{c_1 \ell, n}) = \Omega(2^{\frac{\ell}{2}} \sqrt{n})$ .*

**Proof.** Let  $m = 4$  in the Theorem 4. Then,  $Q(\text{DYCK}_{c_1 \ell, c_2 8^\ell}) = \Omega(4^\ell)$  for some constants  $c_1, c_2 > 0$ . Consider the function  $\text{AND}_{\frac{n}{c_2 8^\ell}} \circ \text{DYCK}_{c_1 \ell, c_2 8^\ell}$  with a promise that  $\text{AND}_k$  has as an input either  $k$  or  $k-1$  ones. The query complexity of this function is  $\Omega\left(\sqrt{\frac{n}{c_2 8^\ell}} 4^\ell\right) = \Omega(2^{\frac{\ell}{2}} \sqrt{n})$ . The computation of the composition  $\text{AND}_{\frac{n}{c_2 8^\ell}} \circ \text{DYCK}_{c_1 \ell, c_2 8^\ell}$  can be straightforwardly reduced to  $\text{DYCK}_{c_1 \ell, n}$  by a simple concatenation of  $\text{DYCK}_{c_1 \ell, c_2 8^\ell}$  instances. ◀

## 5 Quantum complexity of st-Connectivity in grids

### 5.1 Quantum complexity of Directed-2D-Connectivity<sub>n,k</sub>

► **Theorem 7.** *For any  $n \geq k$  and  $\varepsilon > 0$ ,  $Q(\text{DIRECTED-2D-CONNECTIVITY}_{n,k}) = \Omega((\sqrt{nk})^{1-\varepsilon})$ .*

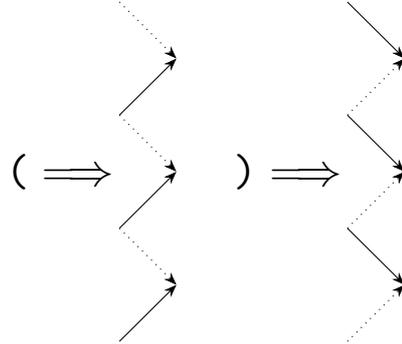

■ **Figure 1** Representation of the Dyck word “(( ))(( ( ))( ))”

383 In particular, if we have a square grid then

384 ► **Corollary 1.** For any  $\epsilon > 0$ ,  $Q(\text{DIRECTED-2D-CONNECTIVITY}_{n,n}) = \Omega(n^{1.5-\epsilon})$ .

385 **Proof of Theorem 7.** For any sequence  $w$  of  $m$  opening and closing parentheses it is possible  
 386 to plot the changes of depth, i.e., the number of opening parentheses minus the number  
 387 of closing parentheses, for all prefixes of the sequence, see Figure 1. We can connect  
 388 neighboring points by vectors  $(1, 1)$  and  $(1, -1)$  corresponding to opening and closing  
 389 parentheses respectively. Clearly  $w \in L_d$  if and only if the path starting at the origin  $(0, 0)$   
 390 ends at  $(m, 0)$  and never crosses  $y = 0$  and  $y = d$ . Consequently a path corresponding to  
 391  $w \in L_d$  always remains within the trapezoid bounded by  $y = 0$ ,  $y = d$ ,  $y = x$ ,  $y = -x + m$ .  
 392 This suggests a way of mapping  $\text{DYCK}_{d,m}$  to the  $\text{DIRECTED-2D-CONNECTIVITY}_{n,k}$  problem:

1. An opening parenthesis in position  $i$  corresponds to a “column” of upwards sloping available edges  $(i - 1, l) \rightarrow (i, l + 1)$  for all  $l \in \{0, 1, \dots, d - 1\}$  such that  $i - 1 + l$  is even. A closing parenthesis in position  $i$  corresponds to downwards sloping available edges  $(i - 1, l) \rightarrow (i, l - 1)$  for all  $l \in \{1, \dots, d\}$  such that  $i - 1 + l$  is even. See Figure 2.
2. The edges outside the trapezoid adjacent to the trapezoid are forbidden (see Figure 3), i.e., it is sufficient to “insulate” the trapezoid by a single layer of forbidden edges. The only exception are the edges adjacent to the  $(0, 0)$  and  $(m, 0)$  vertex as those will be used in the construction (step 4).
3. Rotate the trapezoid by 45 degrees counterclockwise. This isolated trapezoid can be embedded in a directed grid and its starting and ending vertices are connected by a path if and only if the corresponding input word is valid.
4. Finally we can lay multiple independent trapezoids side by side and connect them in parallel forming an  $\text{OR}_t$  of  $\text{DYCK}_{d,m}$  instances; see Figure 4.

■ **Figure 2**  $\text{DYCK}_{d,m}$  to  $\text{DIRECTED-2D-CONNECTIVITY}$  variable mapping

399 This concludes the reduction  $\text{OR}_t \circ \text{DYCK}_{d,m} \leq \text{DIRECTED-2D-CONNECTIVITY}_{n,k}$ , where  
 400  $n = (d + 1)(t - 1) + \frac{m}{2} + 1$  and  $k = \frac{m}{2} + 1$ . By the well known composition result of Reichardt  
 401 [14] we know that  $Q(\text{OR}_t \circ \text{DYCK}_{d,m}) = \Theta(Q(\text{OR}_t) \cdot Q(\text{DYCK}_{d,m}))$ . All that remains is to  
 402 pick suitable  $t$ ,  $d$  and  $m$  for the proof to be complete. Let  $k$  be the vertical dimension of the  
 403 grid and  $k \leq n$ . Then we take  $m = \Theta(k)$ ,  $d = \log m$  and  $t = \frac{n}{d}$ . ◀

404 Constructing a non-trivial quantum algorithm appears to be difficult and we conjecture  
 405 that the actual complexity may be  $\Omega(nk)$ , except for the case when  $k$  is small, compared to

430  $(x_1, \dots, x_{d-1}, x_d)$  to  $(x_1, \dots, x_{d-2}, x_d n_{d-1} + x_{d-1})$  if  $x_d$  is even and to  $(x_1, \dots, x_{d-2}, x_d n_{d-1} +$   
 431  $n_{d-1} - 1 - x_{d-1})$  if  $x_d$  is odd. It is a bijection because  $x_d$  and  $x_{d-1}$  can be recovered from  
 432  $x_d n_{d-1} + n_{d-1} - 1 - x_{d-1}$  by computing the quotient and remainder on division by  $n_{d-1}$ .  
 433 One can view this procedure as “folding” where we take layers (vertices corresponding to  
 434 some  $x_d = l$ ) and fold them into the  $(d-1)$ -st dimension alternating the direction of the  
 435 layers depending on the parity of the layer  $l$ . ◀

436 For directed  $d$ -dimensional grids we can only slightly improve over the  $n^{\frac{d}{2}}$  trivial lower bound.

437 ▶ **Theorem 11.** For directed  $d$ -dimensional grids of size  $n_1 \times n_2 \times \dots \times n_d$  such that  $n_1 \leq n_2 \leq$   
 438  $\dots \leq n_d$  and  $\epsilon > 0$ ,  $Q(\text{DIRECTED-dD-CONNECTIVITY}_{n_1, n_2, \dots, n_d}) = \Omega((n_{d-1} \prod_{i=1}^d n_i)^{\frac{1}{2} - \epsilon})$ .

439 ▶ **Corollary 2.** For directed  $d$ -dimensional grids of size  $n \times n \times \dots \times n$  and  $\epsilon > 0$ ,  
 440  $Q(\text{DIRECTED-dD-CONNECTIVITY}_{n, n, \dots, n}) = \Omega(n^{\frac{d+1}{2} - \epsilon})$ .

441 **Proof of Theorem 11.** For each  $I \in [n_1] \times [n_2] \times \dots \times [n_{d-2}]$  we take a 2-dimensional hard  
 442 instance  $G_I$  of  $\text{DIRECTED-2D-CONNECTIVITY}_{n_{d-1}, n_d}$  having query complexity  $\Omega(n_{d-1}^{1-\epsilon} n_d^{\frac{1}{2}-\epsilon})$ .

443 We then connect them in parallel like so:

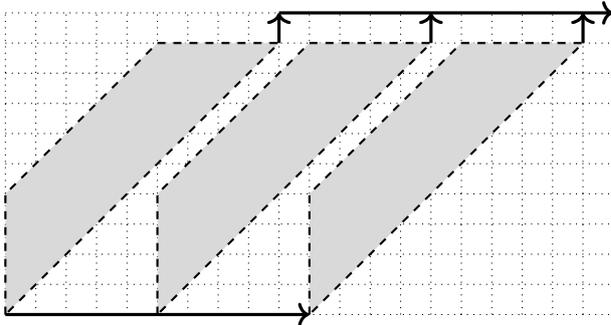

- 444 ■ Make available the entire  $(d-2)$ -dimensional subgrid from  $(1, 1, \dots, 1, 1, 1)$  to  $(n_1, n_2, \dots, n_{d-2}, 1, 1)$   
 445 and similarly the subgrid from  $(1, 1, \dots, 1, n_{d-1}, n_d)$  to  $(n_1, n_2, \dots, n_{d-2}, n_{d-1}, n_d)$ ;
- 446 ■ For each  $I \in [n_1] \times [n_2] \times \dots \times [n_{d-2}]$  embed the instance  $G_I$  in the subgrid  $(I, 1, 1)$  to  
 447  $(I, n_{d-1}, n_d)$ ;
- 448 ■ Forbid all other edges.

449 This construction computes  $\text{OR}_{\prod_{i=1}^{d-2} n_i} \circ \text{DIRECTED-2D-CONNECTIVITY}_{n_{d-1}, n_d}$  whose com-  
 450 plexity is at least  $\Omega(\sqrt{\prod_{i=1}^{d-2} n_i} n_{d-1}^{1-\epsilon} n_d^{\frac{1}{2}-\epsilon}) = \Omega((n_{d-1} \prod_{i=1}^d n_i)^{\frac{1}{2} - \epsilon})$ . ◀

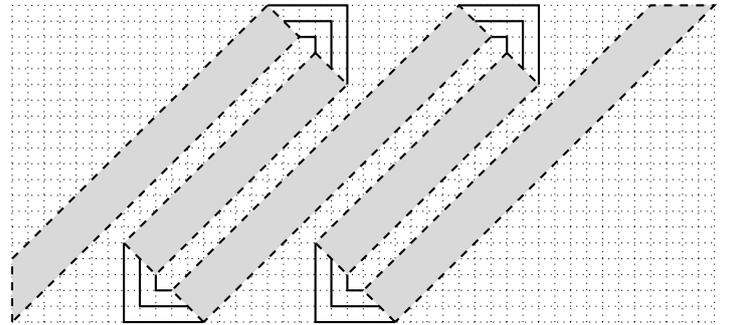

## 451 6 Directions for future works

452 Some directions for future work are:

- 453 1. **Better algorithm/lower bound for the directed 2D grid?** Can we find an  $o(n^2)$   
 454 query quantum algorithm or improve our lower bound? A nontrivial quantum algorithm  
 455 would be particularly interesting, as it may imply a quantum algorithm for edit distance.
- 456 2. **Quantum algorithms for directed connectivity?** More generally, can we come up  
 457 with better quantum algorithms for directed connectivity? The span program method  
 458 used by Belovs and Reichardt [5] for the undirected connectivity does not work in the

■ **Figure 4** Reduction  
 $\text{OR}_t \circ \text{DYCK} \leq \text{DIRECTED-2D-CONNECTIVITY}$

■ **Figure 5** Folding of a long DYCK instance in an undirected grid

459 directed case. As a result, the quantum algorithms for directed connectivity are typically  
 460 based on Grover's search in various forms, from simply speeding up depth-first/breadth-  
 461 first search to more sophisticated approaches [3]. Developing other methods for directed  
 462 connectivity would be very interesting.

- 463 **3. Quantum speedups for dynamic programming.** Dynamic programming is a widely  
 464 used algorithmic method for classical algorithms and it would be very interesting to  
 465 speed it up quantumly. This has been the motivating question for both the connectivity  
 466 problem on the directed 2D grid studied in this paper and a similar problem for the  
 467 Boolean hypercube in [3] motivated by algorithms for Travelling Salesman Problem. There  
 468 are many more dynamic programming algorithms and exploring quantum speedups of  
 469 them would be quite interesting.

520

**B** Proof of Lemma 1

521 The main loop of the algorithm of [9] is the following, assuming the algorithms have error at  
 522 most  $1/9$ :

- 523 ■ for  $m = 0$  to  $\lceil \log_9 n \rceil - 1$  do:
- 524 1. run  $A_m$  1000 times,
  - 525 2. verify the 1000 measurements, each by  $O(\log n)$  runs of the corresponding algorithm,
  - 526 3. if a solution has been found, then output a solution and stop
- 527 ■ Output ‘no solutions’

528 The key of the analysis is that if the (unknown) number  $t$  of solutions lies in the interval  
 529  $[n/9^{m+1}, n/9^m]$ , then  $A_m$  succeeds with constant probability. In all cases, if there are no  
 530 solutions,  $A_m$  will never succeeds with high probability (ie the algorithm only applies good  
 531 solutions).

532 In our case, we allow the algorithm to return anything (including NULL) if  $t < T$ . This  
 533 means that we only care about the values of  $m$  such that  $n/9^m \geq T$ , that is  $m \leq \log_9 \frac{n}{T}$ .  
 534 Hence, we simply run the algorithm with this new upper bound for  $d$  and it will satisfy our  
 535 requirements with constant probability. The complexity is

$$\sum_{m=0}^{\lfloor \log_9 \frac{n}{T} \rfloor} 1000 \cdot O(3^m) + 1000 \cdot O(\log n) = O(3^{\log_9 \frac{n}{T}}) = O(\sqrt{n/T}).$$

## C FindFirst<sub>k</sub> Algorithm's Description, Complexity and Proof of Correctness

### C.1 FindFixedPos<sub>k</sub>

Let us first describe a subroutine used by FINDFIRST<sub>k</sub>.

FINDFIXEDPOS<sub>k</sub>( $l, r, t, s, left$ ) searches for the leftmost substring  $x[i, j]$  such that  $\text{sign}(f(x[i, j])) \in s$  and  $|f(x[i, j])| = k$ , i.e.  $i \leq t \leq j$  and there is no  $x[i', j']$  such that  $i' \leq t \leq j'$ ,  $i' < i$  and  $f(x[i', j']) = f(x[i, j])$ .

The procedure is similar to FINDANY<sub>k</sub>. First, we consider a randomized algorithm that uniformly chooses  $d$  as a power of 2 that is at most  $r - l$ . For this  $d$ , it runs FINDATLEFTMOST<sub>k</sub>( $l, r, t, d, s$ ) algorithm and searches for a non-NULL result. The probability of getting a correct result is at least  $O(1/\log(r-l))$ . Then, we apply the Amplitude amplification method and the idea from Lemma 1 that requires  $O(\sqrt{\log(r-l)})$  iterations. Similarly, we find the maximal  $d$  that finds a substring. This algorithm also performs  $O(\sqrt{\log(r-l)})$  iterations due to [13, 12]. The total complexity of the algorithm is  $O(\sqrt{r-l}(\log(r-l))^{0.5(k-1)})$  due to the complexity of FINDATLEFTMOST<sub>k</sub>.

► **Lemma 12.** FINDFIXEDPOS<sub>k</sub>( $l, r, t, s, left$ ) returns the leftmost minimal substring  $x[i, j]$  such that  $\text{sign}(f(x[i, j])) \in s$  or NULL if there is no such substring. The expected running time is  $O(\sqrt{r-l}(\log(r-l))^{0.5(k-1)})$ .

**Proof.** Let us show by induction that FINDATLEFTMOST<sub>k</sub>( $l, r, t, d, s$ ) returns the leftmost substring  $x[i, j]$  such that  $\text{sign}(f(x[i, j])) \in s$ . If  $k = 2$ , we check whether  $x_t = x_{t-1}$  before  $x_t = x_{t+1}$ .

Assume that there is another minimal substring  $x[i', j']$  such that  $i' \leq t \leq j'$ ,  $f(x[i, j]) = f(x[i', j'])$  and  $i' < i$ .

1. Assume that there are  $j_1$  and  $i_2$  such that  $i < j_1 < i_2 < j$ ,  $|f(x[i, j_1])| = |f(x[i_2, j])| = k-1$  and  $\text{sign}(f(x[i, j_1])) = \text{sign}(f(x[i_2, j])) \in s$ .

By induction one of the invocations of FINDATLEFTMOST<sub>k-1</sub> or FINDFIRST<sub>k-1</sub> finds  $x[i_2, j]$  and it the leftmost. Therefore,  $j' = j$ . If  $i' < i$ , then  $x[i', j']$  is not minimal or  $|f(x[i', j'])| > |f(x[i, j])|$ , a contradiction.

2. Assume that there are  $j_1$  and  $i_2$  such that  $i < i_2 < j_1 < j$ ,  $|f(x[i, j_1])| = |f(x[i_2, j])| = k-1$  and  $\text{sign}(f(x[i, j_1])) = \text{sign}(f(x[i_2, j])) \in s$ . By induction  $x[i_2, j]$  is the leftmost  $\pm(k-1)$ -substring. Therefore,  $j' = j$ . If  $i' < i$ , then  $x[i', j']$  is not minimal or  $|f(x[i', j'])| > |f(x[i, j])|$ , a contradiction.

If  $d > r - l$  the algorithm finds  $x[i, j]$ . If  $d < r - l$ , the algorithm could find the wrong substring (not the leftmost one containing  $t$ ). So, we should to find the maximal  $d$  such that FINDATLEFTMOST<sub>k</sub> finds a substring. In that case, when we amplify the randomized version of the algorithm, we get the required one.

Searching by Grover's search for the maximal  $d$  requires the same  $O(\sqrt{r-l})$  expected number of iterations due to [13, 12]. The total complexity of the algorithm is  $O(\sqrt{r-l}(\log(r-l))^{0.5(k-1)})$  due to the complexity of the FINDATLEFTMOST<sub>k</sub> procedure. ◀

576  $\text{FINDFIXEDPOS}_k(l, r, t, s, \text{right})$  searches for the rightmost substring  $x[i, j]$  such that  
 577  $\text{sign}(f(x[i, j])) \in s$  and  $|f(x[i, j])| = k$ , i.e.  $i \leq t \leq j$  and there is no  $x[i', j']$  such that  
 578  $i' \leq t \leq j'$ ,  $j < j'$  and  $f(x[i', j']) = f(x[i, j])$ .

579 The algorithm is similar to  $\text{FINDFIXEDPOS}_k(l, r, t, s, \text{left})$ , but uses  $\text{FINDATRIGHMOST}_k$ .

## 580 C.2 FindFirst<sub>k</sub> Algorithm's Description

581 The  $\text{FINDFIRST}_k$  procedure calls  $\text{FINDLEFTFIRST}_k$  or  $\text{FINDRIGHTFIRST}_k$  depending on the  
 582 direction. Since both version are essentially symmetric, we only present the search from the  
 583 left below (i.e. when the direction is right). For reasons that become clear in the proof, we  
 584 need to boost the success probability of some calls. We do so by repeating them several  
 585 times and taking the majority: by this we mean that we take the most common answer, and  
 586 return an error in case of a tie.

■ **Algorithm 5**  $\text{FINDRIGHTFIRST}_k(l, r, s)$ . The algorithm for searching for the first  $\pm k$ -substring.

---

```

lBorder ← l, rBorder ← r
d ← 1                                     ▷ depth of the search
while lBorder + 1 < rBorder do
  mid ←  $\lfloor (\textit{lBorder} + \textit{rBorder}) / 2 \rfloor$ 
  vl ←  $\text{FINDANY}_k(\textit{lBorder}, \textit{mid}, s)$            ▷ repeat 2d times and take the majority
  if vl ≠ NULL then
    rBorder ← mid
  if vl = NULL then
    vmid ←  $\text{FINDFIXEDPOS}_k(\textit{lBorder}, \textit{rBorder}, \textit{mid}, s, \textit{left})$    ▷ majority of 2d runs
    if vmid ≠ NULL then
      v ← vmid
      Stop the loop.
    if vmid = NULL then
      lBorder ← mid + 1
  d ← d + 1
return v

```

---

## 587 C.3 Proof of Claim on FindFirst<sub>k</sub> Procedure from Proposition 2

588 Let us prove the correctness of the algorithm for  $\text{direction} = \text{right}$  and  $s = \{+1\}$ . The proof  
 589 for other parameters is similar.

590 First, we show the correctness of the algorithm assuming there are no errors. The  
 591 algorithm is essentially a binary search. At each step we find the middle of the search  
 592 segment  $[\textit{lBorder}, \textit{rBorder}]$  that is  $\textit{mid} = \lfloor (\textit{lBorder} + \textit{rBorder}) / 2 \rfloor$ . There are three  
 593 options.

- 594 ■ There is a  $k$ -substring in  $[\textit{lBorder}, \textit{mid}]$ , then the leftmost  $k$ -substring is in this segment.
- 595 ■ There are no  $k$ -substrings in  $[\textit{lBorder}, \textit{mid}]$ , but  $\textit{mid}$  is inside a  $k$ -substring. If we find  
 596 the leftmost substring containing  $\textit{mid}$ , it is the required substring.
- 597 ■ There are no  $k$ -substrings in  $[\textit{lBorder}, \textit{mid}]$  and  $\textit{mid}$  is not inside a  $k$ -substring. Then  
 598 the required substring is in  $[\textit{mid} + 1, \textit{rBorder}]$ .

599 In each iteration of the loop the algorithm finds a smaller segment containing the leftmost  
 600  $k$ -substring or finds it if it contains  $\textit{mid}$ . We find the  $k$ -substring in the iteration that

601 corresponds to the  $[lBorder, rBorder]$  segment such that  $(rBorder - lBorder)/2 \leq j - i$  or  
 602 earlier.

603 Second, we compute complexity of the algorithm (taking into account the repetitions  
 604 and majority votes). The  $u$ -th iteration of the loop considers a segment  $[lBorder, rBorder]$ .  
 605 The length of this segment is at most  $w \cdot 2^{-(u-1)}$  where  $w = r - l$ . The complexity  
 606 of  $\text{FINDANY}_k(lBorder, mid, s)$  is at most  $O\left(\sqrt{w \cdot 2^{-(u-1)-1}} (\log(w \cdot 2^{-(u-1)-1}))^{0.5(k-1)}\right) =$   
 607  $O\left(\sqrt{w \cdot 2^{-(u-1)-1}} (\log(r - l))^{0.5(k-1)}\right)$ . Also,  $\text{FINDFIXEDPOS}_k(lBorder, rBorder, mid, s, left)$   
 608 has complexity  $O\left(\sqrt{w \cdot 2^{-(u-1)}} (\log(w \cdot 2^{-(u-1)}))^{0.5(k-1)}\right) = O\left(\sqrt{w \cdot 2^{-(u-1)}} (\log(r - l))^{0.5(k-1)}\right)$ .  
 609 So the total complexity of the  $u$ -th iteration is  $O\left(u\sqrt{w \cdot 2^{-(u-1)}} (\log(r - l))^{0.5(k-1)}\right)$ , since at  
 610 the  $u$ -th iteration, we repeat each call  $2u$  times to take a majority. The number of iterations  
 611 is at most  $\log_2 w$ . Let us compute the total complexity of the binary search part:

$$\begin{aligned}
 612 \quad O\left(\sum_{u=1}^{\log_2 w} 2u\sqrt{w \cdot 2^{-(u-1)}} (\log(r - l))^{0.5(k-1)}\right) &= O\left(\sqrt{w} (\log(r - l))^{0.5(k-1)} \sum_{u=1}^{\log_2 w} u (\sqrt{2})^{-(u-1)}\right) \\
 613 &= O\left(\sqrt{w} (\log(r - l))^{0.5(k-1)} \sum_{u=0}^{\infty} (u+1) (\sqrt{2})^{-u}\right) \\
 614 &= O\left(\sqrt{w} (\log(r - l))^{0.5(k-1)} \frac{\sqrt{2}^2}{(\sqrt{2} - 1)^2}\right) \\
 615 &= O\left(\sqrt{w} (\log(r - l))^{0.5(k-1)}\right).
 \end{aligned}$$

617 Finally, we need to analyze the success probability of the algorithm: at the  $u^{\text{th}}$  iteration,  
 618 the algorithm will run each test  $2u$  times and each test has a constant probability of failure  
 619  $\varepsilon$ . Hence for the algorithm to fail (that is make a decision that will not lead to the first  
 620  $\pm k$ -substring) at iteration  $u$ , at least half of the  $2u$  runs must fail: this happens with  
 621 probability at most

$$622 \quad \binom{2u}{u} \varepsilon^u \leq \left(\frac{2ue}{u}\right)^u \varepsilon^u \leq (2e\varepsilon)^u.$$

623 Hence the probability that the algorithm fails is bounded by

$$624 \quad \sum_{u=1}^{\log_2 w} (2e\varepsilon)^u \leq \sum_{u=1}^{\infty} (2e\varepsilon)^u \leq \frac{2e\varepsilon}{1 - 2e\varepsilon}.$$

625 By taking  $\varepsilon$  small enough (say  $2e\varepsilon < \frac{1}{3}$ ), which is always possible by repeating the calls  
 626 a constant number of times to boost the probability, we can ensure that the algorithm a  
 627 probability of failure less than  $1/2$ .

### 628 **D Proof of Theorem 3**

629 **Proof.** Let us show that if  $x'$  contains  $\pm(k+1)$ -substring then one of three conditions of  
 630  $\text{DYCK}_{k,n}$  problem is broken.

631 Assume that  $x'$  contains  $(k+1)$  substring  $x'[i, j]$ . If  $j \geq k+n$ , then  $f(x[i-k, n-1]) > 0$ ,  
 632 because  $f(x'[n, j]) = j - n + 1 \leq k < k+1$ . Therefore, prefix  $x[0, i-k]$  is such that  $f(x[0, i-k-1]) < 0$  or  $f(x[0, n-1]) > 0$  because  $f(x[0, n-1]) = f(x[0, i-k]) + f(x[i-k-1, n-1])$ .  
 633 So, in that case we break one of conditions of  $\text{DYCK}_{k,n}$  problem.  
 634

635 If  $j < k + n$  then  $x[i - k, j - k]$  is  $(k + 1)$  substring of  $x$ .

636 Assume that  $x'$  contains  $-(k + 1)$  substring  $x'[i, j]$ . If  $i < k$ , then  $f(x[0, j - k]) < 0$ ,  
637 because  $f(x'[i, k - 1]) = -(k - i) \geq -k > -(k + 1)$  and  $f(x[0, j - k]) = f(x'[k, j]) =$   
638  $f(x[i, j]) - f(x[i, k - 1])$ . So, in that case the second condition of  $\text{DYCK}_{k,n}$  problem is broken.

639 The complexity of Algorithm 3 is the same as the complexity of  $\text{FINDANY}_{k+1}$  for  $x'$  that  
640 is  $O(\sqrt{n + 2k}(\log(n + 2k))^{0.5k})$  due to Proposition 2.

641 We can assume  $n \geq 2k$  (otherwise, we can update  $k \leftarrow n/2$ ). Hence,

$$642 O(\sqrt{n + 2k}(\log(n + 2k))^{0.5k}) = O(\sqrt{2n}(\log(2n))^{0.5k}) = O(\sqrt{n}(2 \log n)^{0.5k}) = O(\sqrt{n}(\log n)^{0.5k})$$

643 The error probability is the same as the complexity of  $\text{FINDANY}_{k+1}$ . ◀

## 644 **E** Reduction for the proof of Theorem 4

645 Before we describe the reduction in detail, we sketch the main idea. Recall that  $f(x) =$   
646  $|x|_0 - |x|_1$ . Note that

$$647 \text{EX}_{2m}^{m|m+1}(x) = 0 \iff f(x) = 2$$

648

$$649 \text{EX}_{2m}^{m|m+1}(x) = 1 \iff f(x) = 0$$

650 whereas

$$651 \text{DYCK}_{k,n}(x) = 1 \iff \left( \max_{p \text{ - prefix of } x} f(p) \leq k \right) \wedge \left( \min_{p \text{ - prefix of } x} f(p) \geq 0 \right) \wedge (f(x) = 0).$$

652 If we could make sure that the minimum and maximum constraints are satisfied,  $\text{DYCK}_{k,n}$   
653 could be used to compute  $\text{EX}_{2m}^{m|m+1}$ . To ensure the minimum constraint, we map each 0 to  
654 00 and 1 to 01. However, this increases  $f(x)$  by  $2m$  which can be fixed by appending  $1^{2m}$   
655 at the end. Importantly, the resulting sequence  $x'$  has  $f(x') = f(x)$ . The first constraint  
656 (maximum over prefixes) can be fulfilled by having a sufficiently large  $k$ ;  $k = 2m + 3$  would  
657 suffice here. The same idea can be applied iteratively to  $\text{EX}_{2m}^{m|m+1}$  where the inputs, which  
658 could now be the results of functions  $\left( \text{EX}_{2m}^{m|m+1} \right)^{\ell-1} = x_i$ , have been recursively mapped to

$$659 \text{sequences } x'_i \text{ with } f(x'_i) = \begin{cases} 2 & \text{if } x_i = 0 \\ 0 & \text{if } x_i = 1 \end{cases}.$$

660 The reduction formally is as follows.

661 We call a string  $B \in \{0, 1\}^w$  of even length a  $(w, h)$ -sized block with width  $w$  and height  
662  $h$  iff for any prefix  $x$  of  $B$ :  $0 \leq f(x) \leq h$  and either  $f(B) = 0$  or  $f(B) = 2$ .

663 We establish a correspondence between inputs to  $\left( \text{EX}_{2m}^{m|m+1} \right)^\ell$  that satisfy the promise  
664 and  $(w, h)$ -sized blocks  $B$  for appropriately chosen  $w, h$ , so that  $\left( \text{EX}_{2m}^{m|m+1} \right)^\ell = 1$  iff  $f(B) = 0$ .

665 For  $l = 0$  (the input bits), we have 0 corresponding to a  $(2, 2)$ -sized block of 00 and 1 to  
666 a  $(2, 2)$ -sized block of 01.

667 For  $l > 0$ , let us have input bits  $x = (x_1, x_2, \dots, x_{2m})$  of  $\text{EX}_{2m}^{m|m+1}$  satisfying the input  
668 promise. Assume that the bits (that could be equal to values of  $\left( \text{EX}_{2m}^{m|m+1} \right)^{\ell-1}$ ) correspond  
669 to  $(w, h)$ -sized blocks  $B_1, B_2, \dots, B_{2m}$ . Define the sequence  $B' = B_1 B_2 \dots B_{2m} 1^{2m}$ . Then it  
670 is easy to verify the following claims:

671 **1)**  $B'$  is a  $(2m(w + 1), 2(m + 1) + h)$ -sized block;

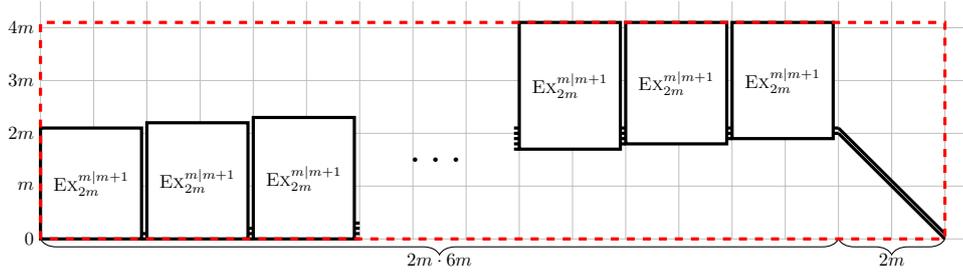

672 2) The output bit of  $\text{EX}_{2^m}^{m|m+1}(x)$  corresponds to  $B'$  because

$$673 \quad f(B') = \sum_{i=1}^{2m} f(B_i) + f(1^{2m}) = \begin{cases} 2 & \text{if } \text{EX}_{2^m}^{m|m+1}(x) = 0 \\ 0 & \text{if } \text{EX}_{2^m}^{m|m+1}(x) = 1 \end{cases} .$$

674 For  $l = 0$ , the inputs correspond to  $(2, 2)$ -sized blocks. Each level adds  $2(m + 1)$  to the  
675 height of the blocks reaching  $2 + 2\ell(m + 1) = O(m\ell)$ . The width of blocks reaches  $O((2m)^\ell)$ .

676 Since for all  $(w, h)$ -sized blocks  $B$ :  $\text{DYCK}_{h,w}(B) = 1 \iff f(B) = 0$  one can solve the  
677  $(\text{EX}_{2^m}^{m|m+1})^\ell$  problem by running  $\text{DYCK}_{h,w}$  on the *corresponding* block.

678 See Figure 6.

■ **Figure 6** The reduction  $\text{EX}_{2^m}^{m|m+1} \circ \text{EX}_{2^m}^{m|m+1} \leq \text{DYCK}_{4m+6, 12m^2+2m}$ . The line of the graph follows the input word along the  $x$ -axis and shows the number of yet-unclosed parenthesis along the  $y$ -axis (i.e., a zoomed-out version of Figure 1). The input word  $B_1 B_2 \dots B_{2^m} 1^{2^m}$  corresponds to the outer function  $\text{EX}_{2^m}^{m|m+1}$  with  $B_j$  being a block corresponding to the output of an inner  $\text{EX}_{2^m}^{m|m+1}$ . The ticks at the starts and ends of blocks depict that if the line enters the block at height  $i$ , it exits at height  $i$  or  $i + 2$ . In the block the line never goes below 0 or above  $h + i$ . The red dashed part then forms a new block  $B'$ . By replacing the blocks  $B_j$  with blocks  $B'$  we can further iterate  $\text{EX}_{2^m}^{m|m+1}$  to get the reduction  $\text{EX}_{2^m}^{m|m+1} \circ (\text{EX}_{2^m}^{m|m+1})^{\ell-1} \leq \text{DYCK}_{O(\ell m), O((2m)^\ell)}$ .

## 679 **F** A quantum algorithm for Directed-2D-Connectivity $_{n,k}$

680 In this section, we prove Theorem 8 by constructing a quantum algorithm for  $\text{DIRECTED-2D-CONNECTIVITY}_{n,k}$ .  
681 The main idea is to construct an AND-OR formula for  $\text{DIRECTED-2D-CONNECTIVITY}_{n,k}$   
682 and to use the quantum algorithm for AND-OR formulae by Reichardt [15] which evaluates  
683 an AND-OR formula of size  $L$  with  $O(\sqrt{L})$  queries.

We first deal with the case when  $n = 2^m$  for some non-negative integer  $m$ . The idea for the construction of the AND-OR formula is to split the grid in two: any path from  $(0, 0)$  to  $(n, k)$  must pass through a vertex  $(n/2, r)$  for some  $r : 0 \leq r \leq k$ . For the paths to and from  $(n/2, r)$  we can apply this reasoning recursively. Let us denote by  $F_{\mu, \kappa, i, j}$  our formula for the path from vertex  $(i, j)$  to  $(i + 2^\mu, j + \kappa)$ , and by  $L_{\mu, \kappa}$  its size (the number of variable instances it has; it does not depend on  $i, j$ ). Thus we have the recurrent formulae

$$F_{\mu, \kappa, i, j} = \bigvee_{r=0}^{\kappa} (F_{\mu-1, r, i, j} \wedge F_{\mu-1, \kappa-r, i+2^{\mu-1}, j+r}),$$

$$L_{\mu, \kappa} = \sum_{r=0}^{\kappa} (L_{\mu-1, r} + L_{\mu-1, \kappa-r}) = 2 \sum_{r=0}^{\kappa} L_{\mu-1, r}.$$

684 For the base case  $F_{0, \kappa, i, j}$  (i. e. for a  $1 \times \kappa$  grid) we simply use an OR of all the paths  
685 (represented as an AND of all its edges). There are  $\kappa + 1$  paths, each of length  $\kappa + 1$ , thus  
686  $L_{0, \kappa} = (\kappa + 1)^2$ .

It follows by induction on  $\mu$  that  $L_{\mu,\kappa} < 2^{\mu+1} \cdot \binom{\kappa+\mu+2}{\kappa}$ . For the induction basis we have  $L_{0,\kappa} < (\kappa+1)(\kappa+2) = 2 \binom{\kappa+2}{\kappa}$ , and for the induction step:

$$L_{\mu,\kappa} = 2 \sum_{r=0}^{\kappa} L_{\mu-1,r} < 2^{\mu+1} \sum_{r=0}^{\kappa} \binom{r+\mu+1}{r} = 2^{\mu+1} \binom{\kappa+\mu+2}{\kappa}.$$

687 Using a well-known upper bound for binomial coefficients we obtain:  $L_{m,k} < 2^{m+1}(e \cdot (k+m+2)/k)^k = O\left(n(e(1 + \frac{\log_2 n}{k}))^k\right)$ . There exists a quantum algorithm with  $O(\sqrt{L})$  queries for a  
 688 formula of size  $L$  [15], thus we obtain the complexity mentioned in the theorem statement.  
 689

690 For an arbitrary  $n$  we can find the smallest  $m$  for which  $n \leq 2^m$  and use the formula for  
 691 the  $2^m \times k$  grid obtained by adding ancillary edges from the vertex  $(n, k)$  to  $(2^m, k)$  (using  
 692 the edge variables of the added part of the grid as constants). Since the value of  $n$  thus  
 693 increases no more than two times, the complexity estimation increases by at most a constant  
 694 multiplier.
